FPGA Development for the LHCb Vertex Locator Upgrade

Nicholas Mead 8064141 School of Physics and Astronomy University of Manchester

January 11, 2016

Abstract

This document discusses two areas of FPGA development for the LHCb VELO upgrade scheduled to coincide with LHC Long Shutdown 2 in 2019. The selection of a suitable scrambling algorithum and the continued work on the event isolation flagging.

10

12

14

16

18

20

The analysis for three scrambling algorithums, required for data transfer from the front end electronics to the Data Aquisition FPGA, was compared against the theoretical predictions of scrambled data. It was found that the currently implimented VeloPix scrambler is the optimum of the choices but also that an alternative multiplicative scrambler was suitable for computer simulations.

Event Isolations Flaging (EIF) system is intended to identify and flag the easier to re-construct events in order to reduce event pill-up in the computer network. While a bug is identified in the simulated data, the VHDL developent has coninued and is ongoing. A bubble sorting algorithum, implemented by the EIF system, is in ready for testing. Once the EIF system is complete, it will be implemented in the master code for the low level interface.

1 Introduction

1.1 The Standard Model of Particle Physics

Central to the moden study of particle physics is the standard model,

$$L_{GWL} = \sum_{f} (\bar{\Psi}_{f} (i\gamma^{\mu}\partial\mu - m_{f})\Psi_{f} - eQ_{f}\bar{\Psi}_{f}\gamma^{\mu}\Psi_{f}A_{\mu}) + \frac{g}{\sqrt{2}} \sum_{i} (\bar{a}_{L}^{i}\gamma^{\mu}b_{L}^{i}W_{\mu}^{+} + \bar{b}_{L}^{i}\gamma^{\mu}a_{L}^{i}W_{\mu}^{-})$$

$$+ \frac{g}{2x_{w}} \sum_{f} \bar{\Psi}_{f}\gamma^{\mu} (I_{f}^{3} - 2s_{w}^{2}Q_{f} - I6e_{f}\gamma_{5})\Psi_{f}Z_{\mu} - \frac{1}{4}|\partial_{\mu}A_{v} - \partial_{v}A_{\mu} - ie(W_{\mu}^{-}W_{v}^{+} - W_{\mu}^{+}W_{v}^{-})|^{2}$$

$$- \frac{1}{2}|\partial_{\mu}W_{v}^{+} - \partial_{v}W_{\mu}^{+} - ie(W_{\mu}^{+}A_{v} - W_{v}^{+}A_{\mu}) + ig'c_{w}(W_{\mu}^{+}Z_{v} - W_{v}^{+}Z_{\mu}|^{2}$$

$$- \frac{1}{4}|\partial_{\mu}Z_{v} - \partial_{v}Z_{\mu} + ig'c_{w}(W_{\mu}^{-}W_{v}^{+} - W_{\mu}^{+}W_{v}^{-})|^{2} - \frac{1}{2}M_{\eta}^{2}\eta^{2} - \frac{gM_{\eta}^{2}}{8M_{W}}\eta^{3} - \frac{g'^{2}M_{\eta}^{2}}{32M_{W}}\eta^{4}$$

$$+ |M_{W}W_{\mu}^{+} + \frac{g}{2}\eta W_{\mu}^{+}|^{2} + \frac{1}{2}|\partial_{\mu}\eta + iM_{Z}Z_{\mu} + \frac{ig}{2c_{w}}\eta Z_{\mu}|^{2} - \sum_{f} \frac{gm_{f}}{2M_{W}}\bar{\Psi}_{f}\Psi_{f}\eta. \quad (1.1)$$

- The standard model shown in equation 1.1, is a quantum field theory that discribes the fundermental particles and how they interact. While this document does not require or attempt a detailed understanding the intricate detail of the stardard model; the aim of many particle physics experiments is to varify, measure and expand the model. Dispite being the current best theory to explain particle interactions, the model is not complete. There are many undescribed phenomina, such as the matter domination in the universe, that require physics beyond the standard model in order to be described. To that end, major international efforts namely in the form of the Large Hardron Collider, aim to gain
- further knowledge and understanding of the underlying physics of the universe. [1]

1.2 Field Programable Gate Arrays

- <u>Field Programable Gate Arrays (FPGAs)</u> are silicon based intergrated circuit chips. Unlike conventional chips, where the circuit and logic gates are perminatly systhesised from
- silicon transistors at manufacture time, the internal structure of an FPGA can be manipulated to the desired structure of the user. The advantage of FPGAs is the high data
- transfer rates and versitility they deliver, withouth the cost of manufacturing purpose build chips. As such, FPGA's are used expencively in the development of new technology
- and small batch size production. [4]
- FPGAs are programed in a variety of languages known as <u>H</u>ardware <u>D</u>escription <u>L</u>andguages (HDLs). One of the more common HDLs and the HDL uses in this project is <u>V</u>ery High Speed Integrated Circuit <u>H</u>ardware <u>D</u>escription <u>L</u>andguages (VHDL). Programing a cir-
- cuit in VHDL requires the creation of entities, sometimes referred to as moduals. These entities can be though of as a 'black boxs' that compute some form of logic on their inputs
- and outputs. The form of this logic computed but the entity is known as the entities architecture.

When building a circuit larger than one simple function it is often nesserary to use more than one entity. In VHDL, entities can contain sub-entities withing thier architecture; entities that do this are known as top-level entities. Top level entities are often used to comute signals between there sub-entities and/or control how to sub-entities operate.

78 1.3 The LHCb Experiment

One experiment at the Large Hadron Colider is Large Hadron Colider beauty (LHCb). Located at intersection point 8, LHCb is designed to study rare particle physics phemonena, such as lepton flavour violation and CP violation. LCHb studies the decay modes of the B meson. These hardons travel in the order of μ m's in the detector before decaying. As such, B meson decays can be identied by decay products that propagate from a secondary vertex.

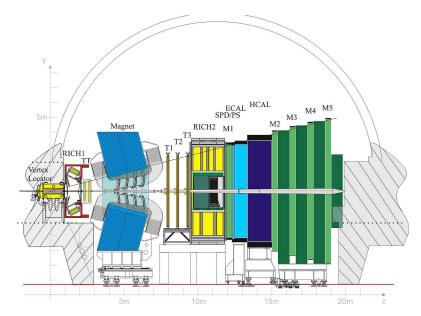

Figure 1.1: The LHCb Detector along the bending plane.

As B mesons are light (in comparision to other particles studied in the LHC), the decay products are produced at a shallow angle relavite the the beam pipe; this is the driving factor in the design of the exeperiment. LHCb is a single arm forward spectormeter. Surrounding the point of collision is the Vertex Locator (VELO), this high precision detector uses silicon strips to detect ionising particles as they propagate from a collition and provides the coordinates of the particle in terms of \mathbb{R}^1 and ϕ^2 . By reconstructing the paths of particles back to the intersection point, it can be identified wether or not the

particular decay particles are a product of the primary vertex³, or a secondary vertex⁴.

The Rich dectector, comprised of two subdectectors eitherside of the magnet, uses cherincov radiation to deduce the velocity of the particle. The silicon trackers, labeled TT

¹Radial distance from the beam pipe.

²Asumthal angle from the beam pipe.

³The position at which the protons collided.

⁴The decay point of a short lived particle. i.e. B Meson.

and T1-3 in Figure 1.1, calculate the angle deflection by the magnet. By combining the velocity and angle of deflection, the mass, momentum and energy of the particles can be decuced from simple relativistic kinematics,

$$E^2 = M^2 c^4 + p^2 c^2. (1.2)$$

The Muon detectors, labeled M1-5 in Figure 1.1, are important to detect muon's the detector. This is of particular importance on LHCb as muons can be easily misidentified as charged Pions, due to there similar mass. Pions are a common decay product of the interactions studied at LHCb, furthering the need to accuratly identify Muon and Pions.

HCAL and ECAL, shown in Figure 1.1, are hadronic and electric calorimeters respectively. Both measure the total energy of incoming particles. As the calorimeters are absorb the particles they detect, any leptonic particle reaching the M2-5 muon detectors can be assumed to be a muon. Electrons and Photons are absorbed by the ECAL and any Tauons would have decayed long before reaching the far muon detectors.

1.4 LHCb Upgrade

With the advancments in accelerator technology, the detectors must also advance in order to make best use of the accelerators. The LHC is schedualing to increase its luminosity during Long Shutdown 2 (LS2), and as such LHCb will have to cope with this greater luminosity. The front end electronics of LHCb implement a hardware trigger and this is limited to a 1MHz maximum readout speed. Post LS2, LHCb will have to cope is a luminosity of $\mathcal{L} = 2.10^{33} cm^{-2} s^{-1}$, this is significantly greater than the current $\mathcal{L} = 4.10^{32} cm^{-2} s^{-1}$. A simple luminosity increase will not significantly increase that statistics for some statistical error dominated channels. To achieve greater statistical significance, greater resolution of the VELO and fully software triggers are required. Detailed in the 'LHCb VELO Upgrade Technical Design Report' [2] the main goals of the 2019 upgrade are as follows:

- Increase the luminosity to $\mathcal{L} = 2.10^{33} cm^{-2} s^{-1}$.
- Read data from the detector at the bunch crossing frequency, 40 Mhz.
- Convert to a purely software bassed trigger.

$_{ m 12}$ 1.4.1 VELO Upgrade

120

Common with its predecessor, the upgraded VELO uses thin, retractable modules. The advange of this approach is that during collisions, the modules can sit closer that otherwise possible to the beam line. The modules retract for the beam fill, avoiding the radiation damage from the wider fill beams. In order to gain greater resolution of secondary verticies, the upgraded VELO will sit at 5.1 mm from the beam at the closest pixel [2]. The current VELO achieves 8 mm [3].

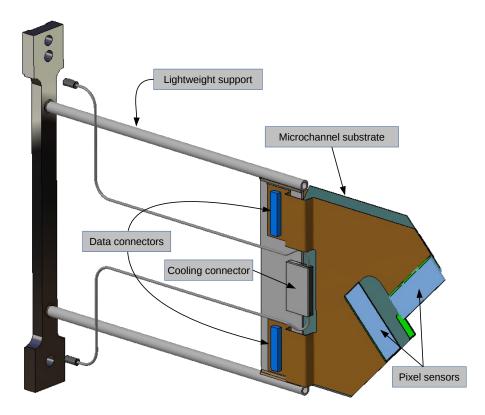

Figure 1.2: The current module design. Two sensors are shown, the remaining two are mounted to the rear face of the module to for two horizontal rows - covering the right most area of the module (as viewed in the figure).

As previously mentioned, the current VELO uses silicon strips to detect particles. The upgraded VELO, however, will use silicon pixels. These pixels, $55\mu m \times 55\mu m$ in size and $200\mu m$ thick [2], are arranged in a 256 wide square matrix on a ASIC chip. The pixels are arranged into groups of 8 to form a Super Pixel (SP). The ASIC chips are arranged in a row of 3 and bonded to a sensor. Each module has 4 sersors, 2 per side, as shown in Figure 1.2. The module is is cooled by bi-phase CO² in micro-channels etched into the microchannel substrate.

The VELO modules will operate in the LHC secondary vacuum. It is seperated from the primary vacuum by RF foil that is 3.5mm from the beamline, at the closest point [2]. The foil is made of 250 μm thick aluminum to reduce the its interaction with the collision decay products.

1.4.2 Data Flow and Low Level Interface

FPGAs are used in the <u>Data Aquisition</u> (DAQ) modules for speed and paralell processing capabilities. The DAQ, in its simplest form, is a series of optical links, a data processing FPGA and a PCIe port for data transfer to the VELO computer system.

The data from each SP is packaged in a 30 bit <u>Super Pixel Packet</u> (SPP). The SPP is comprised of a (form most to least significant bits) 9 bit <u>Bunch Cross ID</u> (BCID); 13 bit

SPP location information (horizontal and vertical coordinates); 8 bit SP hitmat.

A GWT serialiser forms a 128 bit 'frame' comprising of a header (1010), four single bit parity flags and four SPPs. The parity flags indicate the parity of the four SPPs as a validation check for downstream processes. The data then is transmitted via an electrical to optical converter though optical fibers to the DAQ. In the DAQ is the Low Level

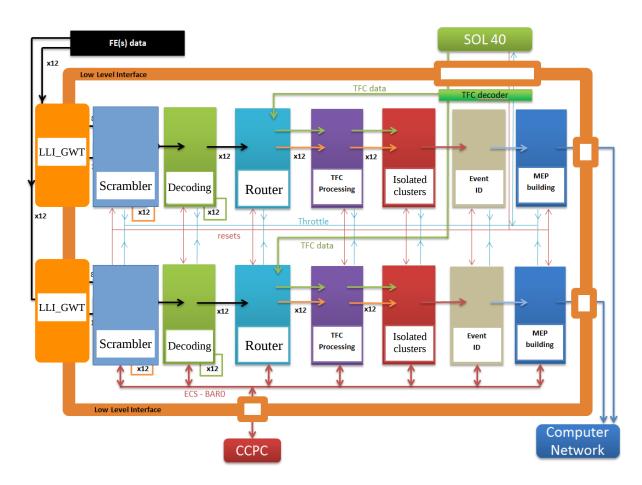

Figure 1.3: A Diagram showing the data flow in the low level interface.

Interface (LLI). The LLI is responsible for sorting the incomming data into time order and packaging the data in the correct form for the computer systems and to optimise output bandwidth. Other processes included in the LLI are descrambling and event isolation tagging. These processes will be discussed in more detail later in this document.

2 Scrambler

150

Due to radiation levels inside the detector chamber, the main data processing takes place in a concrete bunker away from the detector. To facilitate this, 20 optical links (per modual) are used to transfer the data from the front end VELO to the DAQ FPGA. When communicating data digitaly, the transferring modual (TX) and the recieving modual (RX) must have synchronised clocks. In these case, the GWT serialiser is the

TX, and the DAQ is the RX. When achieving synchronised clock, there are two main approaches:

- Transmit the TX clock with the data to the RX modual used in I²C and SPI communication.
- Use bit-changes in the data to continuously synchronise the RX clock.
- The former of these options, although widely used in conventional electronics, requires a finely tuned clock accounting for all possible delays. The latter, while negating cons of the former, requires data with a high density of transitions to reduce the likelihood of a desynchronisation event. Because delays in the data are possible, the latter option has been selected.
- As mentioned, it is necessary to ensure that the data has large density of transitions before being transmitted from the front-end detector to the DAQ modual. However, as the majority of super pixel hitmaps are empty, the data has a bias towards '0's.

 This reduces the frequency of transitions in the data increasing the probability of a desynchronisation event. It is therefor necessary to scramble the data prior to transmition and descramble the data in the LLI of the DAQ FPGA.
- Scrambling and later descrambling the data is not a trivial exercise. The scrambleing (TX) modual and descrambling (RX) modual must use a sychronised 'key', that is used in both the scrambling and descrambling processes. In the FPGA, the 'key' is derived from the previous states of the data. There are two methods investigated for generating this 'key':
- Additive The 'key' is generated by evolving the previous 'key' at each itteration of data using the incoming frame.
- Multiplicative The 'key' is generated from the previos n frames. (Here n is a variable specific to the algorithm).

2.1 Scrambler Options

Three scrambling algorithums have been considered:

188 Additive Scrambler

190

194

164

This scrambler is was originally implemented and used two sets of two-input XOR logic gates. As the name implies, this scrambler used additive key generation which is dependent on all previous input frames since the last reset signal.

192 Intermediate Scrambler

Created by Karol Hennessy, and deriving its name arbitrarily from the order of consideration, this multiplicative scramber combines the current and previous frames to

generate the 'key'. Therefor, in the event of desynchronisation, only two frames are lost before the 'key' is automatically recovered. This feature alone is a significant improvment over the Additive Scrambler.

198 VeloPix Scrambler

196

200

202

204

This is the current implemented scramble algorithum in the DAQ and VeloPix code. Like the Intermediate Scrambler, it uses multiplicative 'key' generation. However, the VeloPix scrambler is compatible with further constraints enforced by the ASIC, including the number of combinational logic operations. The Intermediate Scrambler was design purely for simulation purposes and as such does not meet the additional ASIC constraints.

2.2 Cross Checks

The main priority when scrambling data, is ensuring that the data is recoverable. For all three scramblers, the algorithum was synthesised in Quartus [5] and simulated in Modelsim [6]. The aim of synthesising and simulating the scramblers in these programs was to ensure that the design was both physical in term of on-board logic gates, and to check that the scrambled data was recoverable, respectively.

Furthermore, a C++ simulation was created for the three scramblers. This simulation had two main purposes; firstly to cross check the output of the C++ against the Modelsim simulations; secondly to simulate the scrambler over a much larger sample of data as Modelsim simulations are less time effecient. In addition to the cross checks, the C++ code allowed for the injection of a descrnonisation event, in which the 'key' is lost. As expected, the Additive Scarmbler was unable to recover any data post descrnonisation, however the intermediate and VeloPix scarmblers both recovered the 'key' after two frames and continued to recover data.

2.3 Algorithm Analysis

For analytical purposes, it is assumed that fully scrambled data is indistinguisable from randomly generated data. For this reason, the three algorithms are not only tested against each other and the pre-scrambled QWT data but also randomly generated binary. The randomly generated data was created using the Python 'random' library, selecting a '0' or '1' with equal probability. While the Python 'random' library is only sudo-random, on the scale of this example (i.e. >> 100,000 frames), it is sufficient for theses purposes.

A more mathematically rigorus approach, however, is to evaluate the system abstractly in the framework of statistical physics. In this abstraction, the 120 bit frame (with the header and parity removed) is considered an ensemble; microstates are the particular form of the frames; and macroscopic quantities can be calculated by averaging a large number of frames. For the analysis outlined in section 2.3.1, predictions will be made using these principles and outlined in section 2.3.2.

In the context of the statistical model, it is reasonable to concider the degree of 'scrambledness' analogous to entropy. This analogy is not disimular to the common interpritation of entropy as a measure of dissorder. From Bolzman's equation for entropy,

$$S \sim \ln(\Omega) \tag{2.1}$$

where Ω is the number of microstates associated with the macrostate, we learn that this state of maximum entropy is a macrostate with the maximum number of associated microstates.

The entropic argument of Equation 2.1 is not only mathematical founded. For a scramble algorithum to hold for all possible data sets, it must also be capable of outputing all possible permutations. As such, assuming all possible output are equally likely, the count of each macroscopic output will be proportional to the number of microstates associated.

2.3.1 Messurements of the Algorithms

To compare the effecincy of the three algorithums in section 2.1, the algorithums where run over the same input data and compared for the following measures:

Number of Transitions Per Frame

This measure counts the total number of bit transitions (i.e. $bit(n) \neq bit(n-1)$) in a 120 bit frame. The header and parity information was not included as they are not scrambled. This is an important test as one of the roles of the scrambler is to maximise the number of transitions.

250 Common Bit Chain Length

One of the downfalls of the 'Number of Transitions Per Frame' analysis is that the two hypethetical 20 bit frames,

- a) 1010101010111111111111,
- b) 10011001100110011001,

both with 10 transitions, are considered equally. However, (b) is clearly a more suitable output for data transfer as (a) has a large probability of desynchronisated due to the long chains of '1's in the right most bits. It is therefore also nescssary to evaluate the length of common bit chains within the scrambled data as shorter chains are more suitable for data transfer.

260 Bit Asymetry

246

248

252

254

258

262

264

Pre-scramble, the data had a large bais towards '0's due to the majority of the hitmaps being empty. Scrambled data, via entropic arguments, should show zero bias eitherway. Therefor, by investigating how the number of '1's - '0's evolves over many frames, any bias in the scrambler can be found.

2.3.2 Statistical Predictions

Number of Transitions Per Frame

Consider a particle in a symmetric, descrete time-dependent, two state system,

$$p_0(t) = p_1(t) = 0.5$$
 : $\forall t \in \mathbb{N}$, (2.2)

At each time itteration,

274

276

278

$$p_{i \to j}(t) = 0.5$$
 : $i, j = [0 \ 1], \quad \forall \ t \in \mathbb{N}.$ (2.3)

However, assuming zero bias and detailed balance, as $p_{1\to 0}(t)$ is equal in both probability and importance to $p_{0\to 1}(t)$, the probability of a bit change shall herefore be referred to as $p_{\tau}(t)$.

Over an n step process, analogous to a n bit frame, the probability distribution of the number of transitions N_{τ} is given by Binomial statistics,

$$f(N_{\tau}) = \frac{n!}{N_{\tau}!(n - N_{\tau})!} p^{N_{\tau}} (1 - p)^{n - N_{\tau}}$$
(2.4)

Simplified for the special case $p = p_{\tau} = 0.5$,

$$f_{\tau}(N_{\tau}) = \frac{n!}{N_{\tau}!(n - N_{\tau})!} (p_{\tau})^{n}$$
(2.5)

For n = 120, we can calulate,

$$\langle N_{\tau} \rangle^{Binomial} = \sum_{N_{\tau}=0}^{n-1} N_{\tau} f(N_{\tau}) = n \ p_{\tau} = 60$$
 (2.6)

$$\sigma_{N_{\tau}}^{Binomial} = \sqrt{n \ p_{\tau}^2} = 5.48 \tag{2.7}$$

Furthermore, when considering the entropic argument of equation 2.1, the number of microstates corresponding to each macrostate N_{τ} can be related to equation 2.5,

$$\Omega_{\tau} \sim \frac{n!}{N_{\tau}!(n - N_{\tau})!} \tag{2.8}$$

$$< N_{\tau} > Entropic = MAX[S_{\tau}] = MAX[\Omega_{\tau}]$$
 (2.9)

This can be numerically solved,

$$\langle N_{\tau} \rangle^{Entropic} = 60 \tag{2.10}$$

While the result of equation 2.10 does not contibute anything new, it is important as a 'sanity check'. Because the system can be described as in section 2.3, it would indicated a problem in the theoretical framework if the result did not match.

Common Bit Chain Length

280

282

284

286

288

290

292

298

The probability of a chain of length n is,

$$p_n = p_1(1 - p_\tau)^{n-1}, \quad : \quad n \in \mathbb{N}, \quad n > 1$$
 (2.11)

where p_1 is the number of chains of length 1. As $p_1 = N_0(1 - p_\tau)$, where N_0 is the total number of chains,

$$\frac{N_n}{N_0} = (1 - p_\tau)^n, \quad : \quad n \in \mathbb{N}, \quad n > 1$$
 (2.12)

where N_n in the number of chains of length n. Takeing the log of both sides,

$$log\left(\frac{N_n}{N_0}\right) = n \ log(1 - p_\tau),$$

$$log(N_n) = n \ log(1 - p_\tau) + log(N_0).$$
(2.13)

Therefor, for a graph of $log(N_n)$ against n for a large sample of data, the gradient would be $log(1 - p_{\tau})$. In this case, as $p_{\tau} = 0.5$,

$$log(1 - p_{\tau}) = -0.30 . (2.14)$$

Bit Asymetry

 $A_{1,0}$, the assymetry of '1's and '0's is defined as,

$$A_{1,0} = N_1 - N_0, (2.15)$$

where N_1 and N_0 are the number of '1's and '0's respectively. We can consider the evolution of $A_{1,0}$ with frame t of size n as a stochastic itterative map with zero deterministic growth [7],

$$A_{1,0}(nt + n \Delta t) = A_{1,0}(nt) + \mathcal{N}(nt)$$
 (2.16)

Where \mathcal{N} is an independent random variable picked from a gausian distribution. While $A_{1,0}(t) \in \mathbb{Z}$, in the limit of large nt we can approximate that $A_{1,0}$ is continious. If we consider the moments of $A_{1,0}$,

$$\langle A_{1,0}(nt = M \ n \ \Delta t) \rangle = \sum_{m=0}^{M-1} \mathcal{N}(m \ n \ \Delta t),$$
 (2.17)

$$\langle A_{1,0}(nt = M \ n \ \Delta t)^{2} \rangle = \sum_{m=0}^{M-1} \sum_{m'=0}^{M-1} \mathcal{N}(m \ n \ \Delta t) \mathcal{N}(m' \ n \ \Delta t) \ \delta_{mm'}$$

$$= \sum_{m=0}^{M-1} \langle \mathcal{N}(m \ n \ \Delta t)^{2} \rangle. \tag{2.18}$$

Clearly, in Equation 2.17, $\langle A_{1,0} \rangle = 0$. In Equation 2.18, we assume the variance is of form $(n \Delta t)^{\alpha}$ [7]. Then,

$$< A_{1.0}(nt = M \ n \ \Delta t)^2 > = M(n \ \Delta t)^{\alpha}.$$
 (2.19)

Running the analysis over the frames t=0 to t_f , the number of bits sampled is $M=t_f/n \Delta t$. Substituting this into Equation 2.19,

$$< A_{1,0}(nt = M \ n \ \Delta t)^2 > = t_f \ (n \ \Delta t)^{\alpha - 1}.$$
 (2.20)

Considering the three cases of α in the approximation of continuous $n\Delta t$:

- $\alpha > 1$: Here $A_{1,0} \to 0$ as $\Delta t \to 0$.
- $\alpha < 1$: Here $A_{1,0} \to \infty$ as $\Delta t \to 0$.
 - $\alpha = 1$: This is the only sensible choice.

With $\alpha = 1$,

300

302

304

306

$$< A_{1,0}(nt = M \ n \ \Delta t)^2 > = M(n \ \Delta t).$$
 (2.21)

And thus,

$$\sigma_{A_{1,0}} = \sqrt{\langle A_{1,0}^2 \rangle - \langle A_{1,0}^2 \rangle^2} = \sqrt{\langle A_{1,0}^2 \rangle} = \sqrt{n \Delta t}.$$
 (2.22)

o 2.3.3 Results of Analysis

The results from the 'Number of Transitions Per Frame' analysis, shown in Figure 2.1, show a strong simularity between the Intermediate and VeloPix Scramblers with the randomly generated data. These results are withing 1% agreement with the theoretical predictions for $\langle N_{\tau} \rangle = 60$ and $\sigma_{N_{\tau}} = 5.48$, made in Section 2.3.2. The remarkable consistancy between the theoretical predictions and the randomly gernerated data provides confidance in both the theory, and the scrambled nature of the Intermediate and VeloPix scrambler outputs.

Figure 2.1: Results of the 'Number of Transitions Per Frame' analysis. The results for the Random Data, Intermediate Scrambler and VeloPix Scrambler overlap for the 'Number of Transitions Per Frame' analysis.

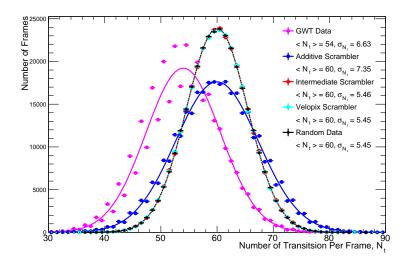

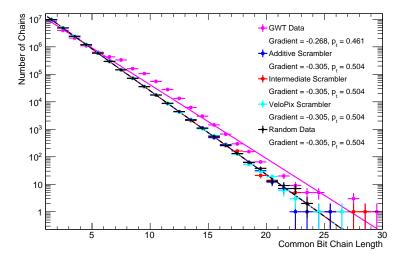

Figure 2.2: Results of the 'Common Bit Chain Length' analysis. The results for the Random Data, Additive Scrambler, Intermediate Scrambler and VeloPix Scrambler approximatly overlap for the 'Common Bit Chain Length' analysis.

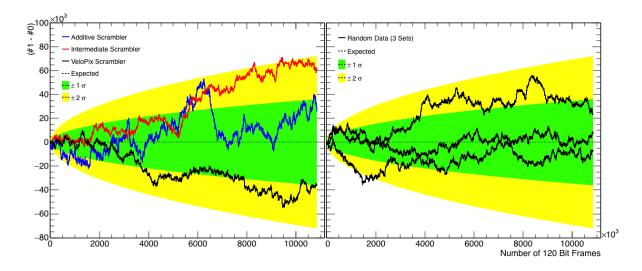

Figure 2.3: The results of the 'Bit Asymetry' analysis.

All three scramblers; the random data, and the theoretical predictions are consistant to within 1%. Comparing the two results for the Additive Scrambler has however shown, that while the frequancy of longer chains is consistant with random data, the variance of transitions is larger than predicted. Thus, the long and short trains are more localy clustered.

The 'Bit Asymetry' of each scrambler, shown in Figure 2.3, is consistant with the theoretical prediction. The deviation of $A_{1,0}$ for the predicted mean of 0 is fully consistant with stochastic noise. The random data also shows consistancy. This gives confidence in the assumtpions made in Section 2.3.2.

2.4 Conclusion

	$ < N_{\tau} >$	$\sigma_{N_{ au}}$	Gradient	$p_{ au}$
GQT data	54	6.63	-0.268	0.460
Additive Scrambler	60	7.35	-0.305	0.504
Intermediate Scrambler	60	5.45	-0.305	0.504
Velopix Scrambler	60	5.46	-0.305	0.504
Random Data	60	5.45	-0.305	0.504
Theoretical Prediction	60	5.48	-0.3	0.5

Table 2.1: The combined results of the algorithum analysis.

The consistancy of random data and the theoretical predictions justifies the assumptions and approximations made in Section 2.3 and Section 2.3.2. Furthermore, the conforma-

- tion of the statistical model allows for accurate comparisons to be made from predicted values and their measured counterparts.
- The Additive Scrambler, while consistant with the 'Chain Length' and 'Bit Asymetry' analysis, has a variance in the transition frequency that leads the conclusion that long and short chains are locally clusted. This is not ideal for data transfer. Many sequential long chains increase the probability of TX-RX clock desychronisation. Furthermore, the additive scrambler will not recover from this loss of synchronisation, as the 'key' will never be recovered without a common reset signal.
- The Intermediate Scrambler produced an output consistant with random data. This makes the algorithm suitable of data transfer. As already mentioned, however, the scrambler is designed for computer simulation. As such, it is not suitable for implementation as it does not meet the additions requirments of the ASIC.
- The VeloPix Scrambler, like the Intermediate Scrambler, produces a statistically scrambled output. Furthermore, the algorithum in inline with the additional requirments of the ASIC. As such, it is ideal for implementation, and hence is currently the choice algorithm for use in the 2019 VELO upgrade.

3 Event Isolation Flagging

- One challange of increasing the readout speed of the detector is prossesing the data that is produced. Because of this, any pre-computer data processing that is possible reduces the load and processing time of the computer system. One area where the DAQ's FPGA will be used for this purpose is in Event Isolation Flagging (EIF).
- Particles traversing the VELO have a probability that they will pass thought the boundry of two or more Super Pixels. This will cause multiple SPPs for the same particle. As such, the reconstruction of the particles path is a more complicated process than a particle path that only interects with one SP.
- The aim of EIF is to identify the SPPs that completly describe the paticles interaction with the modual and flag then event as isolated. These flagged events will allow the computer systems to prioritise these easier to re-construct paths. This reduces event pile up the computer network.

$_{\scriptscriptstyle{50}}$ 3.1 Time Sorting Data

Frames arriving the DAQ from the GWT are not time ordered. When fully implimented, the LLI will have time sorted the data before the EIF. However, the provided simulated data of the VELO not time ordered.

- In order to test any EIF development, it is nessesary to time order the simulation data. This was done using a python script that sorted the SPPs into lists according to BCID.

 The stript has three main phases:
 - Read in SPP and retrieve BCID.
 - Add SPP to correct list according to BCID.
 - Print list of opposite BCID (i.e. input SPP's BCID + 124 accounting for BCID 256 rolling over to 0) to file.

As not all BCID's were present, measures were put in place to ensure all BCID lists where outputed in time order, preventing lists containing SPPs from two or more bunch crosses. The time order of the data was tested and confirmed as correct.

One advantage of this process is that, regardless of the number of isolated events, the data no longer needs to be sorted by the computer network. This further reduced the computational load on the computers.

3.2 Bubble Sorting

368

370

- The first step in EIF is to sort all the SPP's that correspond to the same bunch crossing (Hereforth referred to as a 'data trian') by their row in the ASIC.
- Bubble sorting, when implemented in series processing, is a relitivelty slow sorting algorithum. At worst case, Bubble sorting requires n^2 itterations to complete the sort.
- However, as FPGA's can easily parallel process. By making $\frac{n}{2}$ comparisons simultaniously (all even-odd or odd-even pairs), FPGA Bubble Sorting in the worst case scenario only requires n itterations. This is made clear in Figure 3.1.

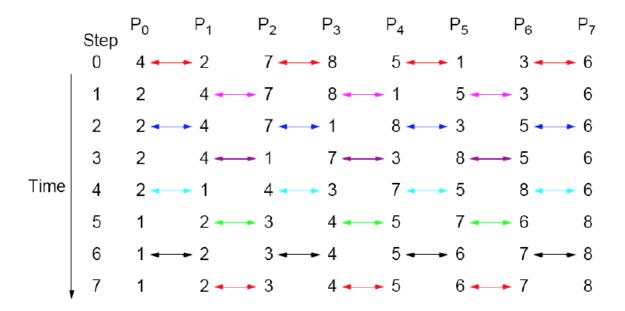

Figure 3.1: A diagram showing Bubble Sorting in an FPGA.

3.3 Isotation Checking

Once the data train is sorted by row, each SPP in the train can be compared against its adjacent SPP's. If the SPP is seperated by > 1 row to both adjacent SPP's, the event is isolated. The SPP is then stored as a 31 bit SPP, with the new bit added as the least significant bit (shifting the original SPP 1 bit in significance), with the new bit signaling 1 for isolated and 0 for non-isolated.

3.4 Data Train Overflow

- One limitation of EIF in an FPGA is the limitation on resources. The logic systems are static in design and as such there is a natural need for a cap on the size of datatrain that the EIF system can accept specifically for the bubble sorting. Because of this limitation, the EIF system is required to implement a overflow sytem that will reject data trains above a pre-determined limit, and move them to the next step of the LLI without processing them. This system is also required to bypass data if a data train arrives at the EIF system before the previous train has been processed preventing pile-up.
- In order to investigate the limit needed for the overflow, the distribution of data train sizes was investigated. For each ASIC, a graph simular to those in Figure 3.2 can be created.
- More important, however, is the faction of data trains over the bypass limit. For four hypothetical limits, the fraction of overflow datatrains was calculated from the VELO simulated data, and it shown in Figure 3.3. This analysis, however, raises questions

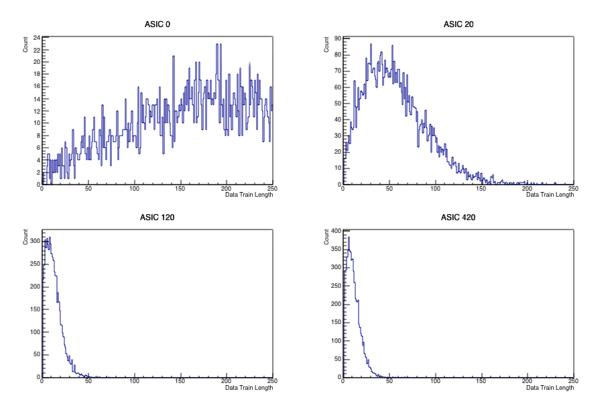

Figure 3.2: The data train length distribution of 4 ASIC chips.

- beyond that of the overflow limit. The ASIC's below 100 show no simulatity to those above 100.
- Further investigations as the to structure of the simulated data is shown in Appendix A.1. From this we learn that large variance in the data (ASIC number > 100) is due to the ASIC's position on the modual. This result is expected as the ASICs closses to the beam line will detect more particle paths. This structure is not consistant across the ACIS's pre and post 100. It can be concuded that the simulated data contains a 'bug' and it now being reviewed by the creators of the simulation. No further analysis can be continued on this front until this 'bug' has been properly investigated.

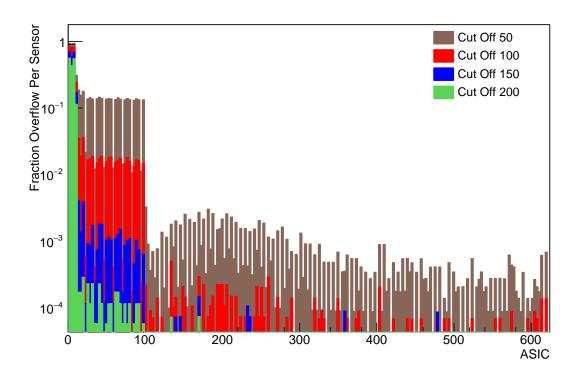

Figure 3.3: fraction of overflow data trains for four overflow limits.

3.5 Current Stage of Development

The EIF system is still currently in active VHDL development. The current developmently code is still in a stand alone format and not intergrated with the master LLI code. Currently created and ready for stand alone testing, is a bubble sorting module with data in and out systems. The module consists of a top level control entity and a comparison/swap sorting entity. The control entity forms a feedback loop passing the ouput of the sorting enity back into its input at each step. At each step, the parity of comparison is changed (i.e. odd-even to even-odd).

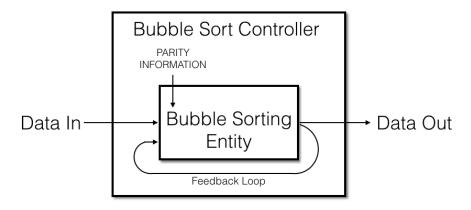

Figure 3.4: Data from for the developmental bubble sorting module.

- This process continues until the input and output of the sorting module is identical for two subsequent steps. At this point the data is sorted and passed to the output. The data flow is more simply demonstrated in Figure 3.4.
- Once testing of the bubble sorting is complete and the simulated data bug is fixed, the EIF will be expanded to include Isolation Flagging and an overflow as discussed. Once the stand alone system is complete, it will be intergrated into the LLI master code and

modified to comply with the LLI data managment systems.
